# An Impossible Counting Problem

Suppose you went to a grocery store to buy some fruits. There are some constraints though:

- A. The store has only two **apples** left: one red and one green.So you cannot take more than 2 apples.
- B. All but 3 **bananas** are rotten. You do not like rotten bananas.
- F. Figs are sold 6 per pack. You can take as many packs as you want.
- M. **Mangoes** are sold in pairs. But you must not take more than a pair of pairs.
- P. They sell 4 **peaches** per pack. Take as many packs as you want.

Now the question is: in how many ways can you buy n fruits from the store?

# **Generating Functions**

*Generating functions* represent sequences by coding the terms of a sequence as coefficients of powers of a variable in a formal power series.

For example, one can represent a sequence  $s_0, s_1, s_2, ...$  as:

$$S(z) = s_0 + s_1 z + s_2 z^2 + s_3 z^3 + \dots + s_n z^n + \dots$$

So  $s_n$  is the coefficient of  $z^n$  in S(z).

# An Impossible Counting Problem

A. The store has only two **apples** left: one red and one green.So you cannot take more than 2 apples.

$$A(z) = 1 + 2z + z^{2} = (1 + z)^{2}$$

B. All but 3 **bananas** are rotten. You do not like rotten bananas.

$$B(z) = 1 + z + z^{2} + z^{3} = \frac{1 - z^{4}}{1 - z}$$

F. **Figs** are sold 6 per pack. You can take as many packs as you want.

$$F(z) = 1 + z^{6} + z^{12} + z^{18} + \dots = \frac{1}{1 - z^{6}}$$

M. **Mangoes** are sold in pairs. But you must not take more than a pair of pairs.  $1-z^6$ 

$$M(z) = 1 + z^{2} + z^{4} = \frac{1 - z^{5}}{1 - z^{2}}$$

P. They sell 4 **peaches** per pack. Take as many packs as you want.

$$P(z) = 1 + z^4 + z^8 + z^{12} + \dots = \frac{1}{1 - z^4}$$

## An Impossible Counting Problem

Suppose you can choose n fruits in  $s_n$  different ways.

Then the generating function for  $s_n$  is:

$$S(z) = A(z)B(z)F(z)M(z)P(z) = (1+z)^2 \times \frac{1-z^4}{1-z} \times \frac{1}{1-z^6} \times \frac{1-z^6}{1-z^2} \times \frac{1}{1-z^4}$$
$$= \frac{1+z}{(1-z)^2}$$
$$= (1+z)\sum_{n=0}^{\infty} (n+1)z^n$$
$$= \sum_{n=0}^{\infty} (2n+1)z^n$$

Equating the coefficients of  $z^n$  from both sides:

$$s_n = 2n + 1$$

### Fibonacci Numbers

Recurrence for *Fibonacci numbers*:

$$f_n = \begin{cases} 0 & if \ n = 0, \\ 1 & if \ n = 1, \\ f_{n-1} + f_{n-2} & otherwise. \end{cases}$$

$$\Rightarrow f_n = f_{n-1} + f_{n-2} + [n=1]$$

Generating function:  $F(z) = f_0 + f_1 z + f_2 z^2 + f_3 z^3 + ...$ 

$$F(z) = \sum_{n} f_{n} z^{n} = \sum_{n} f_{n-1} z^{n} + \sum_{n} f_{n-2} z^{n} + \sum_{n} [n=1] z^{n}$$

$$= \sum_{n} f_{n} z^{n+1} + \sum_{n} f_{n} z^{n+2} + z$$
$$= zF(z) + z^{2}F(z) + z$$

### Fibonacci Numbers

$$F(z) = zF(z) + z^{2}F(z) + z$$

$$\Rightarrow F(z) = \frac{z}{1 - z - z^{2}}$$

$$= \frac{z}{(1 - \varphi z)(1 - \hat{\varphi} z)}, \text{ where } \varphi = \frac{1 + \sqrt{5}}{2} \& \hat{\varphi} = \frac{1 - \sqrt{5}}{2}$$

$$= \frac{1}{\sqrt{5}} \left( \frac{1}{1 - \varphi z} - \frac{1}{1 - \hat{\varphi} z} \right)$$

$$= \frac{1}{\sqrt{5}} \sum_{n} (\phi^{n} - \hat{\phi}^{n}) z^{n}$$

Equating the coefficients of  $z^n$  from both sides:

$$f_n = \frac{1}{\sqrt{5}} \left( \phi^n - \hat{\phi}^n \right) = \frac{1}{\sqrt{5}} \left( \frac{1 + \sqrt{5}}{2} \right)^n - \frac{1}{\sqrt{5}} \left( \frac{1 - \sqrt{5}}{2} \right)^n$$

# Average Case Analysis of Quicksort

# <u>Quicksort</u>

**Input:** An array A[1:n] of n distinct numbers.

**Output:** Numbers of A[1:n] rearranged in increasing order of value. **Steps:** 

- **1. Pivot Selection:** Select pivot x = A[1].
- 2. **Partition:** Use a stable partitioning algorithm to rearrange the numbers of A[1:n] such that A[k] = x for some  $k \in [1, n]$ , each number in A[1:k-1] is smaller than x, and each in A[k+1:n] is larger than x.
- **3. Recursion:** Recursively sort A[1: k 1] and A[k + 1: n].
- **4. Output:** Output *A*[1: *n*].

**Stable Partitioning:** If two numbers p and q end up in the same partition and p appears before q in the input, then p must also appear before q in the resulting partition.

We will average the number of comparisons performed by *Quicksort* on all possible arrangements of the numbers in the input array.

Let  $t_n$  = average #comparisons performed by *Quicksort* on n numbers.

Then

$$t_{n} = \begin{cases} 0 & \text{if } n < 1, \\ n - 1 + \frac{1}{n} \sum_{k=1}^{n} (t_{k-1} + t_{n-k}) & \text{otherwise.} \end{cases}$$

The recurrence can be rewritten as follows.

$$t_n = \begin{cases} 0 & \text{if } n < 1, \\ n - 1 + \frac{2}{n} \sum_{k=0}^{n-1} t_k & \text{otherwise.} \end{cases}$$

The recurrence: 
$$t_n = \begin{cases} 0 & \text{if } n < 1, \\ n-1 + \frac{2}{n} \sum_{k=0}^{n-1} t_k & \text{otherwise.} \end{cases}$$

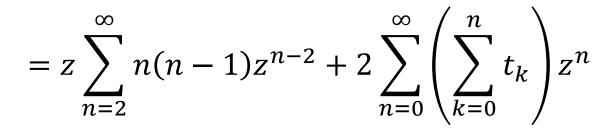

Let T(z) be an ordinary generating function for  $t_n$ 's:

$$T(z) = t_0 + t_1 z + t_2 z^2 + \dots + t_n z^n + \dots$$
$$= t_0 + \sum_{n=1}^{\infty} t_n z^n$$
$$= t_0 + \sum_{n=1}^{\infty} \left( n - 1 + \frac{2}{n} \sum_{k=0}^{n-1} t_k \right) z^n$$

We have: 
$$T(z) = t_0 + \sum_{n=1}^{\infty} \left( n - 1 + \frac{2}{n} \sum_{k=0}^{n-1} t_k \right) z^n$$

Differentiating:

$$T'(z) = \sum_{n=1}^{\infty} \left( n(n-1) + 2\sum_{k=0}^{n-1} t_k \right) z^{n-1}$$

$$= z \frac{d^2}{dz^2} \left( \left( \sum_{n=0}^{\infty} z^n \right) - 1 - z \right) + 2 \sum_{n=0}^{\infty} \left( t_n z^n \left( \sum_{k=0}^{\infty} z^k \right) \right)$$

$$T'(z) = z \frac{d^2}{dz^2} \left( \left( \sum_{n=0}^{\infty} z^n \right) - 1 - z \right) + 2 \sum_{n=0}^{\infty} \left( t_n z^n \left( \sum_{k=0}^{\infty} z^k \right) \right)$$

$$= z \frac{d^2}{dz^2} \left( (1-z)^{-1} - 1 - z \right) + 2(1-z)^{-1} \sum_{n=0}^{\infty} t_n z^n$$

$$= \frac{2z}{(1-z)^3} + \frac{2}{1-z}T(z)$$

Rearranging:  $(1-z)^2 T'(z) - 2(1-z)T(z) = \frac{2z}{1-z}$ 

$$\Rightarrow \frac{d}{dz} \left( (1-z)^2 T(z) \right) = \frac{d}{dz} \left( -2\ln(1-z) - 2z \right)$$

Integrating:  $(1 - z)^2 T(z) = -2 \ln(1 - z) - 2z + c$  (*c* is a constant)

We have,  $(1 - z)^2 T(z) = -2 \ln(1 - z) - 2z + c$  (*c* is a constant)

Putting z = 0,  $T(0) = c \Rightarrow t_0 = c \Rightarrow c = 0$ 

Hence,  $(1-z)^2 T(z) = -2 \ln(1-z) - 2z$ 

$$\Rightarrow T(z) = 2(-\ln(1-z)-z)(1-z)^{-2}$$
$$= 2\left(\sum_{j=2}^{\infty} \frac{z^j}{j}\right) \left(\sum_{k=0}^{\infty} (k+1)z^k\right)$$

Equating coefficients of  $z^n$  from both sides,

$$t_n = 2\left(\sum_{k=2}^n \frac{n+1-k}{k}\right) = 2(n+1)\sum_{k=1}^n \frac{1}{k} - 4n = 2(n+1)H_n - 4n,$$
  
where  $H_n = \sum_{k=1}^n \left(\frac{1}{k}\right)$  is the  $n^{th}$  harmonic number.

We have,  $t_n = 2(n+1)H_n - 4n$ ,

where  $H_n = \sum_{k=1}^n \left(\frac{1}{k}\right)$  is the  $n^{th}$  harmonic number.

But we know,  $H_n = \ln n + O(1)$  (prove it)

Hence,  $t_n = 2(n+1)(\ln n + O(1)) - 4n = \Theta(n \log n)$ .
